COVER STORY

Correcting the Record: Response to the EFF January 15, 2026 Report on Palantir

Editor's Note: This blog post responds to allegations published by the Electronic Frontier Foundation (EFF) in relation to Palantir's work with Immigration and Customs Enforcement (ICE).

Palantir · Palantir Blog

We believe it's important to address misconceptions (as we have previously) about our technology and business practices with transparency and factual accuracy.

The Electronic Frontier Foundation (EFF) has long served as a venerable digital rights organization focused on online civil liberties issues. In the past, EFF's intellectual rigor and careful analysis have served an important function in public discussions about the use of technology. That is why it is particularly important to address instances in which EFF's recent reporting on Palantir got the story wrong.

EFF's January 15, 2026 report , "ICE Using Palantir Tool That Feeds On Medicaid Data" makes a number of misleading and incorrect claims about Palantir's work with the US Federal Government and ICE specifically. Palantir was unfortunately not contacted during the creation of their report, which would have offered us the opportunity to address many of the misconceptions and previously rebutted claims therein.

In the spirit of transparency and open discourse, we outline and respond to these below.

Specific Claims to Address

Here we take specific quotes from the EFF report and, with the aim of good faith transparency, walk through where there may be partial or whole truths, complete inaccuracies, or misleading insinuations that require clarification. We strive to be as exhaustive as possible. We are open to engaging further on these claims with any stakeholders earnestly interested in knowing the real story.

"We also warned about the danger of the Trump administration consolidating all of the government's information

into a single searchable, AI-driven interface with help from Palantir, a company that has a shaky-at-best record on privacy and human rights."

This statement is riddled with tenuous associations and previously rebutted claims. As their core evidence, EFF cites a June 2025 EFF report that uses as a primary reference allegations presented in the May 30, 2025 New York Times article . Palantir thoroughly debunked this NYT article and its core allegations previously: see [Correcting the Record: Responses to the May 30, 2025 New York Times Article on Palantir](#) .

To be absolutely clear, Palantir is not working on any master database project to unify databases across federal agencies. Palantir has not proposed the US Government build a "master list" for the surveillance of citizens, nor have we been asked to consider building such a system for any customer.

EFF's statements misrepresent the fundamental reality of government data sharing across agencies, which is subject to, and governed by, data sharing agreements and government oversight. Further, Palantir is not facilitating widespread and unfettered data sharing across our government customers, as each customer instance of our software is legally, technically, and operationally distinct.

The supposed evidence alleging Palantir's poor "privacy" record cites a September 2020 Privacy International & No Tech For Tyrants report directed at our UK NHS work that reads more as anti-Palantir polemic than factual inquiry. It rehashes a litany of debunked claims about Palantir's

supposed predictive policing work, hollow commitment on PCL protections, lack of transparency in contracting, and questionable relationship to the UK Government. Those allegations have all been addressed in detail on multiple occasions, but notably also in the published annex of that very same report. For more on Palantir's privacy and governance safeguards, see 1, 2, 3, 4.

Similarly, the statement on Palantir's "human rights" record cites to a September 2020 report from Amnesty International, the published annex of which also includes our rebuttals to the claims of the same report. Palantir takes a rigorous approach to respecting human rights, from the development to customer use of our products. We also actively support humanitarian missions around the world, from fighting human trafficking, to disaster relief, to the defense of sovereign nations.

"Palantir is working on a tool for Immigration and Customs Enforcement (ICE) that populates a map with potential deportation targets, brings up a dossier on each person, and provides a "confidence score" on the person's current address," 404 Media reports today. "ICE is using it to find locations where lots of people it might detain could be based."

EFF's restatement of claims by 404 Media is misleading. The ELITE tool is used for prioritized enforcement to surface the likely addresses of specific individuals, such as those with final orders of removal or with high severity criminal charges. The purpose of this tool is identifying the location of known foreign nationals who meet criteria for removal, not for mass prioritization of "locations where lots of people it might detain could be based."

Palantir's role in this tooling centers on data integration, enabling ICE to incorporate data sources to which it has access (including DHS data and limited data shared by other agencies under a data sharing agreement permitting it to be used for immigration enforcement purposes). This data includes information needed by ICE officers and agents to accurately assess whether an individual can be removed, for instance whether an individual has a court-ordered stay on their removal, or whether they have status that precludes their removal.

"The tool — dubbed Enhanced Leads Identification & Targeting for Enforcement (ELITE) — receives peoples' addresses from the Department of Health and Human Services (which includes Medicaid) and other sources, 404 Media reports based on court testimony in Oregon by law enforcement agents, among other sources."

The EFF report is misleading in suggesting that ICE may have, through Palantir software, unfettered access to "multiple government sources including HHS records." While there are instances of limited information sharing between select component agencies of HHS and ICE pursuant to lawful authority, these instances are governed by the same requirements that apply to other components of govern-

ment under the Privacy Act and other applicable laws and policies.

The ELITE tool reported in 404 Media is a component of the capabilities provided under a previously reported pilot program with ICE. As the article explains (and is detailed above), the application supports workflows aimed at prioritizing specific immigration enforcement actions.

Finally, Palantir's platforms are built with an indelible audit log — all platform interactions, from data ingest onwards, are subject to detailed logging. Palantir's platforms are designed with privacy, security, and auditability at their core which, as we've said before, make them exceptionally poor tools for abuse.

"This kind of consolidation of government records provides enormous government power that can be abused. Different government agencies necessarily collect information to provide essential services or collect taxes, but the danger comes when the government begins pooling that data and using it for reasons unrelated to the purpose it was collected."

Indeed, these are real risks. Which is why we've clarified — in responses to both the NYT and the Wyden/AOC letter — that we are not building a "master database" for the Federal Government. Such a hypothetical project would be fundamentally at odds with Palantir's values and our commitment to work in support of liberal democracies.

Moreover, we support efforts to enforce strong privacy protections in government systems, which is why we are advocating for Privacy Act reform. Palantir has been on the cutting-edge of privacy-enhancing technology since our company's inception. It is the cornerstone of what we do.

"While couched in the benign language of eliminating government 'data silos,' this plan runs roughshod over your privacy and security."

This statement mistakenly represents Palantir's work with the US Government. All of Palantir's government contracts and the corresponding deployments of software instances are unique to the contracting agency, with legal, procedural, and technical guardrails in place to protect each agency's data.

It is also wrong to suggest that any sharing (or so-called 'merging') of data across partner agencies implies malicious intent. One need only query terms like 'government data usage' or 'data sharing agreement' to understand the shape and commonality of efforts by Federal Government agencies to cooperate on initiatives involving limited, purpose-specific information sharing to support legitimate cross-agency workflows. This is a routine aspect of government functioning in the modern age. Further, privacy is not guaranteed by a decentralized, siloed series of government systems in which there is no audit trail or visibility into how data is shared or used. All that is guaranteed by such a fragmented data landscape is that abuse of data sharing

and privacy will be harder to systematically guard against or monitor.

“But litigation isn’t enough. People need to keep raising concerns via public discourse and Congress should act immediately to put brakes on this runaway train that threatens to crush the privacy and security of each and every person in America.”

We couldn’t agree more about the importance of public discourse. But the obligation of engaging in public discourse is to do so honorably, in good faith, and with a commitment to facts over all. We are disappointed by the resurfacing of previously debunked or otherwise incorrect claims furthering a narrative that Palantir is leading an effort to spy on Americans and run roughshod over the privacy of our fellow citizens. This is not happening and the principles that underpin our work guard against such misuse of our products.

Palantir has long shared EFF’s commitment to privacy, civil liberties, and security for Americans, and we would have welcomed the opportunity to address the many incorrect claims in their report prior to publication.

We recognize the complexity that our work with the US Government presents, especially during such polarizing times. Palantir has worked with the US Government for two decades and across multiple administrations, and we see it as our enduring mission to support those who work tirelessly to help our institutions function, even when that work is controversial.

We are committed to transparency around the development and responsible use of our products, and hope that future reporting on us focuses on good faith dialogue — that which prioritizes the preservation of humanity in the global commons over conformity to hysteria and polarization. As Hannah Arendt said, “we humanize what is going on in the world and in ourselves only by speaking of it, and in the course of speaking of it we learn to be human.”

Correcting the Record: Response to the EFF January 15, 2026 Report on Palantir was originally published in Palantir Blog on Medium, where people are continuing the conversation by highlighting and responding to this story.

Frontend Engineering at Palantir: Redefining Real-Time Map Collaboration

Palantir · Palantir Blog

How we built lightweight, real-time map collaboration for teams operating at the edge.

Frontend engineering at Palantir goes far beyond building standard web apps. Our engineers design interfaces for mission-critical decision-making, build operational applications that translate insight to action, and create systems that handle massive datasets — thinking not just about what the user needs, but what they need when the network is unreliable, the stakes are high, and the margin for error is zero.

This series pulls back the curtain on what that work really looks like: the technical problems we solve, the impact we have, and the approaches we take. Whether you're just curious or exploring opportunities to join us, these posts offer an authentic look at life on our Frontend teams.

In this blog post, Leon, a Full Stack engineer based in NY, shares how building Gaia's Follow Along mode — his first frontend project at Palantir — shifted his perspective on frontend engineering, while diving into the unique challenges of enabling real-time collaboration at scale.

Before joining Palantir, I thought frontend engineering was mostly about adding pixels, pushing them around, and making things look nice. While that's certainly a component of frontend development, it's nowhere close to the complete picture of what frontend engineering looks like here. At Palantir, frontend engineers are deeply involved in solving complex, novel problems that demand creativity, technical rigor, and close collaboration across teams.

My perspective didn't change overnight — it changed through first-hand experience. Gaia Follow Along Mode was one of my first projects at Palantir, and it perfectly captured just how different frontend engineering is here.

Palantir Gotham is Palantir's platform for integrating, analyzing, and operationalizing complex data in mission-critical defense and intelligence environments. Used by American and allied forces worldwide, Gotham enables teams to collaborate seamlessly, share situational awareness, and make informed decisions — even in challenging operational contexts.

At the heart of Gotham's geospatial capabilities is Gaia, our collaborative map application. Gaia enables teams to analyze and share geospatial data in real time, providing a common operating picture across distributed environments. The Follow Along feature in Gaia allows users to "follow" another user's actions — tracking their cursor, zooming, panning, and selection activity as it happens.

This feature is particularly valuable in defense and other mission-critical environments, where teams are often distributed across remote bases and must operate under severe bandwidth constraints and high network latency.

Traditional screen sharing is often impractical or even impossible in these settings; even when video conferencing is available, the resulting screen shares are low resolution or laggy. Operational users need a lightweight, reliable way to share situational context — one that doesn't consume precious bandwidth, is resilient to latency, and doesn't require high-end connectivity.

Follow Along is a feature that addresses the shortcomings of traditional screen sharing by transmitting only essential state (such as map position, cursor location, and other select information), and sending updates only as changes occur, rather than continuously streaming every frame of the screen. This approach enables real-time collaboration without the heavy network load of true screen sharing.

On the surface, it might look like a simple feature, but building it required thoughtful engineering across multiple dimensions:

Real-time collaboration: Developing a real-time collaborative feature introduced several unique challenges.

Shared state: We needed to reliably synchronize user actions across multiple clients, ensuring that every interaction was reflected almost instantly for all participants. To achieve this, Follow Along leverages an internal shared-state streaming framework, along with libraries such as Redux, to track and update specific map and selection properties in real time. Each client subscribes to updates for the relevant artifact, and only users with the appropriate permissions can participate.

Ordered updates: To guarantee consistency, we introduced a monotonically increasing update index for cursor events, ensuring updates are processed in order and preventing jumpy or inconsistent cursor movement for followers.

Follower chaining and control: We had to handle follower chaining and prevent circular follows (where users could end up following each other in a loop), and ensure seamless hand-offs when a follower wanted to take control.

Disconnection handling: We had to gracefully handle disconnections. For example, if the leader disconnected, the Follow Along session would automatically end for all followers. However, to account for poor network connectivity and intermittent disconnections, we implemented a timeout that waits 15 seconds after the leader disconnects before ending the session for the follower.

Performance: Our users are often deployed in austere environments, where bandwidth is low, latency is high, and compute and hardware resources are limited. To maintain a smooth and responsive experience, we made careful optimizations to minimize resource usage and maximize reliability.

Selective data streaming: Given the restrictive network bandwidth, we had to carefully scrutinize the data included in our updates. While our maps can support large-scale

How robust is our accelerometer?

group · RealClimate

Guest commentary from Nathan Lenssen (Colorado School of Mines)

A new analysis of historical temperatures suggests that things are getting warmer faster, but what does it mean for the future?

As I'll discuss further below, there was no detectable acceleration in the raw GMT series – this doesn't mean there isn't any, but that the noise (internal variability etc.) doesn't allow us to see if there is clearly. Thus, the study has detected an acceleration in the rate of warming of inferred long-term trends – which we can pretty confidently attribute to anthropogenic effects. This study has understandably gotten substantial attention in the media. Here, I will outline what I think we have learned from this study, what this means for our understanding of the current state of the climate system, and what it means for projections of climate change (Hint: not much).

FR26 make three contributions in this recent work: (1) the production of an “adjusted” GMT series that removes statistically estimated impacts of a few short term changes in GMT, to hopefully leave just the warming associated with changes in anthropogenic forcings, (2) the detection of an acceleration in the rate of warming on this series using three different statistical methods, and (3) a forecast that 1.5°C warming will be reached by 2030. The methods used here are generally sound, particularly by engaging with the state of the art in changepoint detection methods as one of the methods for acceleration detection (Beaulieu et al. 2024). The figure below shows the three statistical methods for detecting changes in trend, all of which provide statistically significant evidence that the recent trend is faster than previous trends.

Given the assumptions made by the authors, this provides statistically robust evidence that acceleration has been detected. On first glance, this may be surprising or alarming as, to the zeroth order from our understanding of the Earth's system's response to CO₂, we expect a roughly generally linear warming in GMT given the exponential rise in CO₂ due to the log-scaling of GMT with CO₂. Acceleration could be the result of the decrease of cooling anthropogenic forcings (as is hypothesized for some regional accelerations detected in Beaulieu et al. 2024) or substantial feedbacks/tipping points that are causing the Earth to warm faster than the simple CO₂ forcing physics dictates. Note though that the climate models that are used to inform our future projections also expect an acceleration around now (of course, given the assumptions that went into them).

However, as the authors point out, their method of ‘removing’ ENSO could be improved (for instance, Compo and Sardeshmukh (2010)), and there is still some imprint of natural climate variability in their adjusted time series. Note that an estimate of the “true” natural variability of

the climate system, and correspondingly the “true” forced response, is one of the white whale problems in climate science! FR26 does an credible, but necessarily imperfect, job of isolating the forced response, but don't account for this uncertainty in their statistical tests.

Note though that the climate models that are used to inform our future projections also expect an acceleration around now (of course, given the assumptions that went into them).

group

While we can't know the true internal variability perfectly, we have climate models which provide an estimate of this variability. The figure below shows that the CMIP6 models (screened for a likely Transient Climate Response (TCE)) have a spread that fully contains the observed climate signal. Notably, the ensemble mean of these models demonstrates a slightly greater than linear warming (minus the effects 1991 eruption of Mount Pinatubo).

We can look at this more closely. If we look at the trends in individual model simulations for the last 13 years (2013-2025) and the 13 years before that (2000-2012), on average, the models show a slight acceleration over the same period highlighted by FR26 (0.18°C to 0.30°C). However, while there is a difference in the mean of these distributions, they are not clearly separate. This shows that, at least in model land, the acceleration in trend (given the internal variability and model uncertainty) is going to be difficult to detect. Note that comparisons between the models and the real world are complicated by any divergences in the forcings in the scenarios (designed more than 15 years ago) and what actually happened (Hunga Tonga, the IMO regulations, Chinese aerosol decreases etc.).

Figure 3. CMIP6 trends over the last 13 years (red) and the 13 years before (black) (using the screened simulations), along with the estimate trends from FR26 over (roughly) the same periods.

So where does this leave us? There is no detectable acceleration in the raw observed GMT, but there is an acceleration in GMT when removing the linear effects of ENSO, volcanoes, and solar variability, and there is slight acceleration in GMT when estimated using a multi-model ensemble of climate models. John Kennedy recently discussed some of these results in the context of FR26, expanding to a wider discussion of estimates of warming rate. He hits the nail on the head by pointing out two key open questions: “If there is an acceleration, what is physically driving it?” and “What will happen to the warming rate in the future?” The question about mechanism is key to trustworthy predictions of the future rate, and this is not addressed in the new paper.

The prediction of 1.5°C warming by 2030 made in FR26 is made in this context by estimating the rate of warming in this adjusted GMT. While this is a reasonable forecast,

NASA Selects Intuitive Machines to Deliver Artemis Science, Tech to Moon

Ivry Artis · NASA Breaking News

A rendering of the Intuitive Machines larger cargo class lunar lander is pictured above with the Honeybee Robotics lunar rover (lower right) and the Australian Space Agency's Roo-Ver lunar rover (lower left).

NASA has awarded Intuitive Machines of Houston, \$180.4 million to deliver NASA-funded science and technology to the lunar surface as part of the agency's CLPS (Commercial Lunar Payload Services) initiative and Artemis program. This lunar delivery, which includes seven payloads — five of them NASA's — is expected to increase understanding of the chemical composition and structure of regolith, as well as the radiation environment in and around the South Pole region. This science will continue to build a sustainable human presence by future Artemis missions.

"NASA continues to progress lunar science and exploration by enabling commercial lunar landings," said Joel Kearns, deputy associate administrator for exploration, Science Mission Directorate, at NASA Headquarters in Washington. "These science and technology investigations aim to support long-term sustainability and contribute to a deeper understanding of the lunar surface, test technologies, and prepare for future human missions at the South Pole."

Intuitive Machines is responsible for delivering end-to-end payload services to the lunar surface, targeted to land at the Moon's South Pole region in 2030. This is the fifth CLPS contract for the company, which has delivered payloads to the Moon twice with their IM-1 and IM-2 missions.

"As NASA prepares to send humans and more robotic missions to the Moon, regular CLPS deliveries will provide a better understanding of the exploration environment, accelerating progress toward establishing a long-term human presence on the Moon, setting the stage for eventual human missions to Mars," said Adam Schlesinger, manager of the CLPS initiative at NASA's Johnson Space Center in Houston.

The rovers and instruments, totaling 165 pounds (75 kilograms) in collective mass include:

Stereo Cameras for Lunar Plume Surface Studies (SCALPSS) will use enhanced stereo imaging photogrammetry, active illumination, and ejecta impact detection sensors to capture the impact of the engine exhaust plume on lunar regolith as the lander descends on the Moon's surface. This payload flew on both Intuitive Machines' IM-1 and Firefly Aerospace's Blue Ghost Mission 1 and captured first of its kind imagery. The high-resolution stereo images will aid in creating models to predict lunar regolith erosion and ejecta characteristics, which is important as bigger, heavier spacecraft and hardware are delivered to the Moon near each other. Lead organization: NASA's Langley Research Center in Hampton, Virginia

Near-Infrared Volatiles Spectrometer System (NIRVSS) will observe light emitted or reflected by the lunar soil to help identify its composition. NIRVSS is designed to detect minerals and various types of ices that may be present. NIRVSS will also take high resolution images of the lunar soil and composition variability, which could help inform how ices interact with the lunar soil. The instrument successfully powered on and collected data while in flight on Astrobotic's Peregrine Mission One in 2024. NIRVSS aims to measure the surface temperature at fine scales, which may help determine where ice can exist or remain stable. Lead organization: NASA's Ames Research Center in California's Silicon Valley

Mass Spectrometer for Observing Lunar Operations (MSolo) will characterize the makeup of volatiles (things that easily evaporate) in the environment around the lander following touchdown. The mass spectrometer demonstrated its gas analysis capabilities in lunar conditions during Intuitive Machines' IM-2 mission in 2025. MSolo measures low molecular weight volatiles, which can be used as resources on the lunar surface. Lead organization: NASA's Kennedy Space Center in Florida

Lunar Vehicle Radiation Dosimeter system (LVRaD), a suite of four radiation detectors, is designed to quantify the radiation environment on the lunar surface and assess its potential impacts of radiation on biology and the human body in preparation for future human-related activities on the Moon. Additional sensors will investigate volatiles and geological resources that will help us plan for long-term exploration, as well as gain insights into the Moon's formation and solar system evolution. Lead organization: Korea Astronomy and Space Science Institute

Multifunctional Nanosensor Platform (MNP) is a highly compact and sensitive chemical analysis instrument designed to advance understanding of the lunar environment. It will investigate how exhaust plumes from a lander's engines interact with the lunar regolith by measuring volatile compounds over time and at varying distances from the landing site. These measurements will provide critical data to better understand plume-surface interactions and their effects, informing the design of safer, more sustainable landing systems and surface operations, directly supporting NASA's broader lunar exploration objectives. To enable these measurements, the MNP instrument will be integrated into the Australian Space Agency's rover ("Roo-ver"), a foundation services technology demonstration. The rover will showcase Australia's robotics capabilities, with the ability to traverse complex terrain and operate with limited human intervention. In doing so, Roo-ver will validate key mobility and autonomy technologies in the lunar environment while serving as the enabling platform for MNP's scientific objectives.

Lead organization for MNP: NASA's Goddard Space Flight Center in Greenbelt, Maryland

Lead organization for Rover: Australian Space Agency

Gas price jump feels like a lot because it is

Nathan Yau · FlowingData

For NYT's the Upshot, Francesca Paris gives context to the recent spike in gas prices in the United States :

It's the second-largest four-week increase in at least 30 years — bigger than the one at the start of the war in Ukraine in 2022, or the ones associated with the post-recession surge of 2009 and the OPEC production cuts in 1999 .

The only bigger jump came after Hurricane Katrina in 2005, when gas supply fell significantly .

Rising everyday expenses probably don't help the situation. For those keeping track, 50 Cent is currently adjusted to 111 Cent as of this writing.
